STEER FEEDERS...

problems associated with cattle going on feed

Digestive disorders and a slight transient depression in appetite in newly-arrived cattle in the feedlot have been problems for a number of years. There are numerous causes:

1. The sudden change in type of feed, for example, from grass and milk to grain, silage and/or hay and a protein supplement.
2. Too rapid pushing of grain concentrates.
3. Too much protein
4. Not enough roughage.
5. Too much high quality roughage.
6. Unpalatable feed.
7. Too much green chopped legume or grass silage.
8. Feeding soft or immature corn. If not moldy, soft corn is satisfactory, but animals must be accustomed to it gradually (Morrison).
9. Too much green chopped corn causing green corn poisoning.
10. Too much silage fed to lighter weight calves. Calves do not have the digestive capacity to obtain their total digestible nutrients from a full feed of silage alone.
11. Digestive disorders caused by infections.
12. In addition, in connection with supplements containing an antibiotic, there is an adjustment of the rumen microflora to the antibiotic. This may cause a slight depression in rumen function and reduce appetite for 24 to 36 hours after the initial feeding. Softer feces also may be noticed. This effect is transient and after 36 to 48 hours the appetite should be restored to normal.

For a successful and profitable steer feeding program designed to minimize these problems contact any Miller & Bushong Service Representative or call us direct at Lancaster, 392-2145.
