

How crax differ on feed lines

MAYTOWN — One hundred eggs were sampled each month in June and July 1980 from SCW Leghorn layers in cages being fed from an outgoing feed line, these were compared to 200 eggs gathered from birds on an incoming feed line

An average of eight percent cracked eggs were produced on outgoing as well as incoming feed lines, so there were no differences in the total average number of cracked eggs produced whether birds were eating fresh, home mixed feed from the bin or feed that had traveled several hundred feet past several thousand birds eating at it

Percent cracked eggs between samples had no variation between samples on the outgoing feed lines but varied eight percent (four to 12 percent) between monthly samples on the return feed line

Also specific gravity of eggs produced was only slightly different with three percent more eggs reaching 1.080 specific gravity on the outgoing feed chain production area.

Variation between samples was zero on the outgoing feed line while there was 14 percent variation in specific gravity of eggs between monthly samples on the return feed line

Haugh units were measured by the egg break out method on all eggs and found to have little variation in AA quality eggs between samples on each line, however, only 77 percent eggs were produced on outgoing lines while an average of 86 percent AA eggs were produced by birds on return lines

An average of eight percent blood spots were produced on outgoing feed while only four percent bloods were produced on return feed lines.

An average of 23 percent of all 200 eggs sampled were dirty on the return line while only 17 percent of the 200 eggs were dirty on the outgoing line. Translucent shelled varied only one percent between the outgoing (16 percent translucent shells on eggs) and the return feed line (15 percent translucent shells on eggs).

Average B shells and body checks ran seven percent of all eggs on the outgoing line while only six percent on the return line.

In summary when comparing egg from birds on outbound feedlines, they lead in percent bloods in eggs, while birds on return feed lines lead in percent dirty and percent AA interior quality eggs. No difference was observed in percent cracked eggs or B shells on eggs from birds fed

by outbound feed chains compared to returning feeder lines

It is believed that there may be a behavioral difference in birds on inbound feed line having to compete more, hunt more or work more to get feed. This may be a factor that needs study
