# **Incoming Feeder Cattle** Management

COLUMBUS, Ohio - For any cattlemen, this can be an extremely difficult time for receiving feeder cattle. Frequently, during fall, reports circulate about outbreaks of BRSV, BVD and other related respiratory problems that may be categorized as "shipping fever" in purchased feeder cattle. It seems in many cases, the problems go back to cattle that were not vaccinated as part of a weaning, marketing or receiving program.

## Vaccination

Ohio State University Extension veterinarian Bill Shulaw has said that while vaccines don't solve the problem, they do raise the level of disease resistance when administered to healthy cattle. While it's best to vaccinate before shipment, this is not always possible in the case of purchased feeder cattle.

Incoming cattle should be evaluated upon arrival and if they are in good condition, vaccination will be of benefit if administered with a minimal amount of stress on the calf. Vaccinations for BRSV, BVD, concern for calves destined for the feedlot.

## Feed Intake

Of equal importance in regard to preventing health problems in feeder cattle is proper nutrition. However, a key point to keep in mind is that the best diet one can formulate will result in nutritional deficiencies if calves won't consume it! Newly arrived calves do not readily eat upon arrival in the feedlot.

In fact, OSU Extension Beef Specialist Steve Boyles says on day one in the feedlot, only 22% of the calves may eat. By day 3, approximately 40% may still not be eating and on day 10, an average of 15% of the calves may not be eating.

Factors which stimulate feed intake will increase nutrient intake and allow a quicker recovery from stress and a more immunologically competent animal. When cattle first arrive at an unfamiliar facility, they will spend considerable time walking the fence line searching for a way out.

Boyles says, if possible, feed bunks and water troughs should be located along the fence line so that as cattle circle the pen, they are forced to walk around them. This however may not be a feasible practice for some feedyards.

## Nutrition

The actual starter ration should contain from 70% to 85% concentrate so as to compensate the low intake of incoming calves. If silage is to be a part of the receiving program, consider providing it at least 2 times a day to prevent deterioration in the bunk.

Nutrient content of the starter ration may also be higher to compensate for the reduced feed intake. Starter diets should contain approximately .3 ppm Selenium, 1.0% Potassium on a dry matter basis.

Protein content needs to be higher as well (16-18%).

**Grass and Hay** 

Good quality, long stem grass or legume-grass hay that is free from mold and weeds should be placed in the feed bunk or on the apron their first few days in the pen in order to entice the calves to the bunk. Also, beginning with the first day in the lot, the receiving ration should be sprinkled on top of the grass or grasslegume hay. Boyles says to use a starter ration amounting to between .5 and .75% of the calf's body weight to begin.
