Since the caterpillar has made its appearance this season, the question as to whether it really turns into a butterfly has been frequently asked and will be answered in the following brief description. The eggs, from which the caterpillar is hatched, are laid at a suitable place and in from five to ten days, depending upon the difference in the atmosphere, the eggs are hatched and a small larva or caterpillar, appears. When first hatched, the caterpillar is about a fourth of an inch in length, but by feeding rapidly it increases in size and is full grown in about two weeks, when it measures about one inch in length. After feeding voraciously for about twelve days, it ceases eating and seeks some secluded place to change into the chrysalis or pupa stage. This may be on fences or rubbish, or, as frequently observed, on the outer walls of unpainted buildings. When a suitable place is found the caterpillar spins from its mouth a chrysalis for a hammock. It remains in this sleeping state for sometime when the transformation from the larva to the pupa is complete, and instead of an active caterpillar there will be a stiff chrysalis occupying the place. Then by two successive stages of struggles the chrysalis shell is broken and a new butterfly comes out. Each female butterfly then lays from 100 to 200 eggs which undergo the four stages (the egg, the larva, the pupa, the invago or adult) as above mentioned. Anvone, by a little careful search can collect all four of these stages during the summer months.
