into groups, whereis the species belonging to same group have a somewhat similar extension, while each of the groups is confined to special elimatological conditions, and is found only in those parts were the conditions corres-ponding with its nature prevail. The flora is generally monotonous, but there are certain places dependent partly, per-haps, on the character of the soil, but as much upon exposure to the sun and protection from the changeableness of

000. the coast climate, where a rich vegeta-tion may be found. The flora is destitute of peculiarly characteristic species, because it has come to the country by immigration after the glacial peroid, from other countries which were free from ice at that time. This immigration must have taken place during repeated changes of climate. "After several thousands of years with a severer climate that favored the immigration and extension of nothern and castern species, other thousands of years followed with a milder climate. During this period fresh immigrants came from the south and south-west, compelling the other flora to retreat. In this manner the climate must have changed several time since the glacial age, and the distribution of plants must have changed in accordance therewith. The periods of variation are reflected in the present flora, and it is the former which led to the great gaps in the

extension of coast as well as inland plants. The sunny acrees, the slate districts and the most coast tracts are asylums where the different floras have found refuge. In the intermediate parts they have been dislodged by the new-comers. But certain species, being indifferent to the variations, extended constantly, at the expense of others, and this is the reason of the Norwegian flora being so monotonous."
